ABSTRACT: A high step-up dc–dc converter for a distributed generation system is proposed in this paper. The concept is composed of two capacitors, two diodes, and one coupled inductor. Two capacitors are charged in parallel, and are discharged in series by the coupled inductor. Thus, high step-up voltage gain can be achieved with an appropriate duty ratio. The voltage stresses on the main switch and output diode are reduced by a passive clamp circuit. Therefore, low resistance R_{DS} (ON) for the main switch can be adopted to reduce conduction loss. In addition, the reverse recovery problem of the diode is alleviated. The operating principle and steady-state analysis of the voltage gain are also discussed in detail.

Finally, a MATLAB/Simulink based model is developed with 24v input voltage to obtain 400v output voltage and 400w output power from the proposed converter is simulated in this project.

KEYWORDS: step-up dc–dc converter, distributed generation system, high step-up voltage gain.

1. INTRODUCTION

The distributed generation (DG) systems based on the renewable energy sources have rapidly developed in recent years. These DG systems are powered by micro sources such as fuel cells, photovoltaic (PV) systems, and batteries. Fig. 1.1 shows a PV distributed system in which the solar source is low dc input voltage.

PV sources can also connect in series to obtain sufficient dc voltage for generating ac utility voltage; however, it is difficult to realize a series connection of the PV source without incurring a shadow effect. High step-up dc–dc converters are generally used as the frontend converters to step from low voltage (12–40 V) to high voltage (380–400 V). High step-up dc–dc converters are required to have a large conversion ratio, high efficiency, and small volume.

Distributed energy resource (DER) systems are small-scale power generation technologies (typically in the range of 3 kW to 10,000 kW) used to provide an alternative to or an enhancement of the traditional electric power system. The usual problems with distributed generators are their high costs.

II. PROPOSED CONVERTER

This Proposed Converter has a high efficiency, high step-up voltage gain, and clamp-mode converter. The proposed converter adds two pairs of additional capacitors and diodes to achieve high step-up voltage gain. The coupled inductor is used as both a forward and flyback type; thus, the two capacitors can be charged in parallel and discharged in series via the coupled inductor. The transit current does not flow through the main switch compared with earlier studies. Thus, the proposed converter has low conduction loss. Additionally, this converter allows significant weight and volume reduction compared with other converters. Another benefit is that the voltage stresses on the main switch and output diode are reduced. However, the leakage inductor of the coupled inductor may cause high power loss and voltage spike. Thus, a passive clamping circuit is needed to recycle the leakage-inductor energy of the coupled inductor and to clamp the voltage across the main switch. The reverse-recovery problems in the diodes are alleviated, and thus, high efficiency can be achieved.

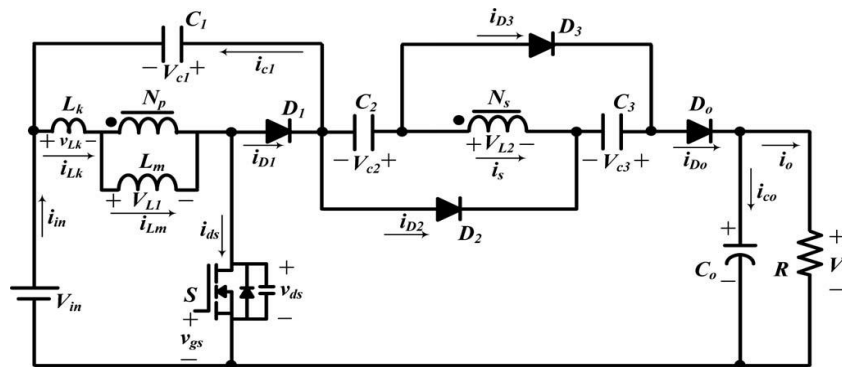

Figure.1. Circuit Configuration of the proposed converter

2.1 Operation

This converter consists of dc input voltage V_{in} , power switch S , coupled inductors N_p and N_s , one clamp diode D_1 , clamp capacitor C_1 , two blocking capacitors C_2 and C_3 , two blocking diodes D_2 and D_3 , output diode D_o , and output capacitor C_o . The coupled inductor is modeled as the magnetizing inductor L_m and leakage inductor L_k .

To simplify the circuit analysis, the following conditions are assumed.

- 1) Capacitors C_2 , C_3 , and C_o are large enough that V_{c2} , V_{c3} , and V_o are considered to be constant in one switching period.
- 2) The power MOSFET and diodes are treated as ideal, but the parasitic capacitor of the power switch is considered.
- 3) The coupling coefficient of coupled inductor k is equal to $L_m / (L_m + L_k)$ and the turns ratio of coupled inductor n is equal to N_s / N_p .

2.2 Continuous-Conduction Mode (CCM) Operation

In CCM operation, there are six operating modes in one switching period of the proposed converter. The operating modes are described as follows.

Mode I [t_0 , t_1]: During this time interval, S is turned on. Diodes D_1 , D_2 , and D_3 are turned off and D_o is turned on. The current-flow path is shown in Fig.2. The primary-side current of the coupled inductor i_{Lk} is increased linearly. The magnetizing inductor L_m stores its energy from dc source V_{in} . Due to the leakage inductor L_k , the secondary-side current of the coupled inductor i_s is decreased linearly. The voltage across the secondary side winding of the coupled inductor v_{L2} , and blocking voltages V_{c2} and V_{c3} are connected in series to charge the output capacitor C_o and to provide the energy to the load R . When the current i_s becomes zero, dc source V_{in} begins to charge capacitors C_2 and C_3 via the coupled inductor. When i_{Lk} is equal to i_{Lm} at $t = t_1$, this operating mode ends.

Vol. 3, Issue 9, September 2014

Figure.2. Current flowing path of proposed converter CCM Mode I operation.

Mode II [t1 , t2]: During this time interval, *S* is still turned on. Diodes *D1* and *Do* are turned off, and *D2* and *D3* are turned on. The current-flow path is shown in Fig. 3. The magnetizing inductor *Lm* is stored energy from dc source *Vin* . Some of the energy from dc source *Vin* transfers to the secondary side of the coupled inductor to charge the capacitors *C2* and *C3*. Voltages *Vc2* and *Vc3* are approximately equal to *nVin* . Output capacitor *Co* provides the energy to load *R*. This operating mode ends when switch *S* is turned off at $t = t2$.

Figure.3. Current flowing path of proposed converter CCM Mode II operation.

Mode III [t2 , t3]: During this time interval, *S* is turned off. Diodes *D1* and *Do* are turned off, and *D2* and *D3* are turned on. The current-flow path is shown in Fig. 4. The energies of leakage inductor *Lk* and magnetizing inductor *Lm* are released to the parasitic capacitor *Cds* of switch *S*. The capacitors *C2* and *C3* are still charged by the dc source *Vin* via the coupled inductor. The output capacitor *Co* provides energy to load *R*. When the capacitor voltage $V_{in} + V_{ds}$ is equal to *Vc1* at $t = t3$, diode *D1* conducts and this operating mode ends.

Figure.4. Current flowing path of proposed converter CCM Mode III operation.

Mode IV [t3 , t4]: During this time interval, *S* is turned off. Diodes *D1* , *D2* , and *D3* are turned on and *Do* is turned off. The current-flow path is shown in Fig.5. The energies of leakage inductor *Lk* and magnetizing inductor *Lm* are released to the clamp capacitor *C1* . Some of the energy stored in *Lm* starts to release to capacitors *C2* and *C3* in parallel via the coupled inductor until secondary current *is* equals to zero. Meanwhile, current *iLk* is decreased quickly. Thus, diodes *D2* and *D3* are cut off at $t = t4$, and this operating mode ends.

Vol. 3, Issue 9, September 2014

Figure.5. Current flowing path of proposed converter CCM Mode IV operation

Mode V [t_4, t_5]: During this time interval, S is turned off. Diodes D_1 and D_o are turned on, and D_2 and D_3 are turned off. The current-flow path is shown in Fig.6. The energies of leakage inductor L_k and magnetizing inductor L_m are released to the clamp capacitor C_1 . The primary and secondary windings of the coupled inductor, dc sources V_{in} , and capacitors C_2 and C_3 are in series to transfer their energies to the output capacitor C_o and load R . This operating mode ends when capacitor C_1 starts to discharge at $t = t_5$.

Figure.6. Current flowing path of proposed converter CCM Mode V operation

Mode VI [t_5, t_6]: During this time interval, S is still turned off. Diodes D_1 and D_o are turned on, and D_2 and D_3 are turned off. The current-flow path is shown in Fig.7. The primary-side and secondary-side windings of the coupled inductor, dc sources V_{in} , and capacitors, C_1 , C_2 , and C_3 , transfer their energies to the output capacitor C_o and load R . This mode ends at $t = t_6$ when S is turned on at the beginning of the next switching period.

Figure.7. Current flowing path of proposed converter CCM Mode VI operation

Figure.8. Some typical key waveforms of the proposed converter at CCM operation.

2.4 Dis-Continuous Conduction Mode (DCM) Operation

In order to simplify the analysis for DCM operation, leakage inductor L_k of the coupled inductor is neglected. There are three modes in DCM operation. The operating modes are described as follows.

Mode I [t_0, t_1]: During this time interval, S is turned on. The current-flow path is shown in Fig.9. The part energy of dc source V_{in} transfers to magnetizing inductor L_m . Thus, i_{Lm} is increased linearly. The dc source V_{in} also transfers another part energy to charge capacitors C_2 and C_3 via the coupled inductor. The energy of the output capacitor C_o is discharged to load R . This mode ends when S is turned off at $t = t_1$.

Figure.9. Current flowing path of proposed converter DCM Mode I operation

Mode II [t_1, t_2]: During this time interval, S is turned off. The current-flow path is shown in Fig.10. The energy of the magnetizing inductor L_m is released to the capacitor C_1 . Similarly, capacitors C_2 and C_3 are discharged in a series with dc source V_{in} and magnetizing inductor L_m to the capacitor C_o and load R . This mode ends when the energy stored in L_m is depleted at $t = t_2$.

Vol. 3, Issue 9, September 2014

Figure.10. Current flowing path of proposed converter DCM Mode II operation

Mode III [t₂, t₃]: During this time interval, *S* remains turned off. The current-flow path is shown in Fig.11. Since the energy stored in *L_m* is depleted, the energy stored in *C_o* is discharged to load *R*. This mode ends when *S* is turned on at *t* = *t*₃.

III. STEADY STATE ANALYSIS

3.1.CCM Operation

At modes IV and V, the energy of the leakage inductor L_k is released to the clamped capacitor $C1$. According to previous work, the duty cycle of the released energy can be expressed as

$$D_{c1} = \frac{t_{c1}}{T_s} = \frac{2(1-D)}{n+1} \quad (1)$$

where T_s is the switching period, D_{c1} is the duty ratio of the switch, and t_{c1} is the time of modes IV and V. By applying the voltage-second balance principle on L_m , the voltage across the capacitor $C1$ can be represented by

$$V_{c1} = \frac{D}{1-D} \cdot V_{in} \cdot \frac{(1+k) + (1-k)n}{2} \quad (2)$$

Since the time durations of modes I, III, and IV are significantly short, only modes II, V, and VI are considered in CCM operation for the steady-state analysis. In the time period of mode II, the following equations can be written based on Fig. 3.

$$v_{L1}^{II} = \frac{L_m}{L_m + L_{k1}} V_{in} = kV_{in} \quad (3)$$

$$v_{L2}^{II} = nv_{L1}^{II} = nkV_{in} \quad (4)$$

Thus, the voltage across capacitors $C2$ and $C3$ can be written as

$$V_{c2} = V_{c3} = v_{L2}^{II} = nkV_{in} \quad (5)$$

During the time duration of modes V and VI, the following equation can be formulated based on Fig.7

$$v_{L2}^V = v_{L2}^{VI} = V_{in} + V_{c1} + V_{c2} + V_{c3} - V_o \quad (6)$$

Thus, the voltage across the magnetizing inductor L_m can be derived as

$$v_{L1}^V = v_{L1}^{VI} = \frac{v_{L2}^{VI}}{n} = \frac{V_{in} + V_{c1} + V_{c2} + V_{c3} - V_o}{n} \quad (7)$$

Using the volt-second balance principle on L_m , the following equation is given:

$$\int_0^{DT_s} v_{L1}^{II} dt + \int_{DT_s}^{T_s} v_{L1}^{VI} dt = 0 \quad (8)$$

Substituting (2), (3), (5), and (7) into (8), the voltage gain is obtained as

$$M_{CCM} = \frac{1+nk}{1-D} + nk + \frac{D}{1-D} \cdot \frac{(1-k)(n-1)}{2} \quad (9)$$

The ideal voltage gain is written as

$$M_{CCM} = \frac{1+n}{1-D} + n \quad (10)$$

According to the description of the operating modes, the voltage stresses on the active switch S and diodes $D1$, $D2$, $D3$, and D_o are given as

$$V_{DS} = \frac{1}{1-D} V_{in} = \frac{V_o - nV_{in}}{n+1} \quad (11)$$

$$V_{D1} = \frac{1}{1-D} V_{in} = \frac{V_o - nV_{in}}{n+1} \quad (12)$$

$$V_{D2} = V_{D3} = V_{D_o} = \frac{n}{1-D} V_{in} = \frac{n}{n+1} (V_o - nV_{in}) \quad (13)$$

Equations (11)–(13) mean that with the same specifications, the voltage stresses on the main switch and diodes can be adjusted by the turn's ratio of the coupled inductor.

International Journal of Advanced Research in Electrical, Electronics and Instrumentation Engineering

(An ISO 3297: 2007 Certified Organization)

Vol. 3, Issue 9, September 2014

3.2. DCM Operation

In DCM operation, three modes are discussed. The key waveform is shown in Fig. 5. During the time of mode I, the switch S is turned on. Thus, the following equations can be formulated based on Fig.9

$$v_{L1}^I = V_{in} \quad (14)$$

$$v_{L2}^I = nV_{in}. \quad (15)$$

The peak value of the magnetizing inductor current is given as

$$I_{Lmp} = \frac{V_{in}}{L_m} DT_s. \quad (16)$$

Furthermore, the voltage across capacitors $C2$ and $C3$ can be written as

$$V_{c2} = V_{c3} = v_{L2}^I = nV_{in}. \quad (17)$$

In the time interval of mode II, the following equations can be expressed based on Fig.10

$$v_{L1}^{II} = -V_{c1}, \quad (18)$$

$$v_{L2}^{II} = V_{in} + V_{c1} + V_{c2} + V_{c3} - V_o. \quad (19)$$

During the time of mode III, the following equation can be derived from Fig.2.11

$$v_{L1}^{III} = v_{L2}^{III} = 0. \quad (20)$$

Applying the voltage-second balance principle on Np , Ns of the coupled inductor, the following equations are given as

$$\int_0^{DT_s} v_{L1}^I dt + \int_{DT_s}^{(D+D_L)T_s} v_{L1}^{II} dt + \int_{(D+D_L)T_s}^{T_s} v_{L1}^{III} dt = 0 \quad (21)$$

$$\int_0^{DT_s} v_{L2}^I dt + \int_{DT_s}^{(D+D_L)T_s} v_{L2}^{II} dt + \int_{(D+D_L)T_s}^{T_s} v_{L2}^{III} dt = 0. \quad (22)$$

Substituting (14), (15), (17), (18), (19), and (20) into (21) and (22), the voltage gain is obtained as follows:

$$V_{c1} = \frac{D}{D_L} V_{in} \quad (23)$$

$$V_o = \left[\frac{D}{D_L} (n+1) + (2n+1) \right] V_{in}. \quad (24)$$

According to (24), the duty cycle DL can be derived as

$$D_L = \frac{(1+n)DV_{in}}{V_o - (1+2n)V_{in}}. \quad (25)$$

IV. SIMULINK MODELS AND RESULTS

The MATLAB/Simulink model of the proposed converter under full load condition ($P_o=400W$) is shown in Fig.4.1. The output voltage 400v obtained is shown in Fig.4.2. The proposed converter is operated in CCM under full-load condition. The corresponding diode voltage and current waveforms are shown in Fig's.4.3-4.11. Fig.4.3 Output voltage waveform for proposed converter in CCM operation at V_{ds} is clamped at appropriately 70v. Fig. 4.5 Output current waveform for proposed converter in CCM operation at I_S is clamped at appropriately 10A. Fig's.4.7&4.8 the Output current waveforms of I_{d2} and I_{d3} show that capacitors $C2$ and $C3$ are charged in parallel. The diode currents I_{D2} and I_{D3} are clamped at appropriately 8A. V. CONCLUSION

A step-up dc–dc converter is designed and Simulated in this project. By using the capacitor charged in parallel and discharged in a series by the coupled inductor, a high step-up voltage gain is achieved. The steady-state analysis of voltage gain is discussed in detail. Simulation results confirm that high step-up voltage gain is achieved. Moreover, the proposed converter has simple structure. It is suitable for renewable energy systems in microgrid applications.
